📄 Final Report: Global Pollution Analysis and Energy Recovery

1. Introduction

This project focuses on analyzing global pollution data to understand its impact on energy recovery and to explore how pollution can be converted into a useful energy resource. Using data analysis and machine learning techniques, the study aims to identify patterns, predict energy recovery, and classify pollution severity levels.

---

2. Dataset Description and Preprocessing

The dataset used contains information about:

- Air, water, and soil pollution indices
- CO_2 emissions
- Industrial waste generation
- Energy consumption and recovery
- Country and year

Preprocessing Steps:

- Missing values were handled using mean imputation.
- Categorical variables such as country were encoded using Label Encoding.
- Pollution indices were normalized using StandardScaler.
- Column names were standardized (lowercase, no spaces).
- A new feature, **energy consumption per capita**, was created for better insights.

---

3. Exploratory Data Analysis (EDA)

EDA was performed to understand patterns and relationships in the dataset:

- **Descriptive statistics** revealed the distribution and variability of pollution and energy metrics.

- **Correlation analysis** showed strong relationships between:
    - CO_2 emissions and energy recovery
    - Industrial waste and energy generation
- **Visualizations** (line plots, heatmaps, boxplots) helped identify:
    - Trends over time
    - Outliers in pollution levels
    - Differences across countries

---

4. Model Development and Evaluation

4.1 Linear Regression Model

- **Objective:** Predict energy recovery (GWh)
- **Input Features:**
    - Air Pollution Index
    - CO_2 Emissions
    - Industrial Waste

Performance Metrics:

- R^2 Score: Indicates how well the model explains variance
- Mean Squared Error (MSE): Measures prediction error
- Mean Absolute Error (MAE): Average error magnitude

Observation:

The model showed a reasonable ability to predict energy recovery, indicating that pollution metrics are strong predictors of energy generation potential.

4.2 Logistic Regression Model

- **Objective:** Classify pollution levels (Low, Medium, High)
- **Input Features:**

- Air Pollution Index
- CO_2 Emissions

Performance Metrics:

- Accuracy
- Precision, Recall, F1-score
- Confusion Matrix

Observation:

The model effectively classified pollution levels, with good accuracy and balanced performance across categories.

---

5. Model Comparison

Aspect	Linear Regression	Logistic Regression
Type	Regression	Classification
Output	Continuous (Energy Recovery)	Categories (Pollution Levels)
Metrics	R^2, MSE, MAE	Accuracy, F1-score
Use Case	Prediction	Categorization

Conclusion:

- Linear Regression is useful for **quantifying energy recovery potential**
- Logistic Regression is useful for **categorizing pollution severity**
- Both models complement each other in decision-making

---

6. Key Findings

1. Higher pollution levels are strongly associated with higher energy recovery potential.
2. Industrial waste plays a major role in energy generation.
3. Some countries show high pollution but low energy recovery, indicating inefficiency.

4. Moderate pollution levels offer balanced opportunities for both reduction and energy optimization.

---

7. Actionable Recommendations

1. Waste-to-Energy Implementation

Countries with high industrial waste should invest in technologies that convert waste into energy.

2. Strengthening Environmental Policies

Strict emission regulations can help control excessive pollution levels.

3. Focus on High-Potential Regions

Countries with high pollution and low energy recovery should prioritize infrastructure improvements.

4. Integration with Renewable Energy

Combining pollution-based energy recovery with solar and wind can improve sustainability.

5. Data-Driven Decision Making

Governments and industries should use predictive models to monitor trends and optimize strategies.

---

8. Conclusion

This project demonstrates that pollution, when managed effectively, can be transformed into a valuable energy resource. By combining data analysis with machine learning, it is possible to both predict energy recovery and classify pollution severity. The insights derived can help policymakers and industries make informed decisions for a more sustainable future.
